

What moved the score, and how we know

$\Delta \text{val_bpb}$ of each change against its control (negative = better). The fill shows the kind of evidence; n is the number of comparisons where the repo records it.

Source: docs/FINDINGS.md sections 1, 3 and 5. Bars with no n are quoted there without a pair count: read them as single comparisons, mostly on earlier recipe bases. Ranges show two measurements. Chip pairs are same-seed, same-chip; raw pairs include any step-time cost.
